

Tableau Prep - Ability to remove field in Join step

Nearly every time a join is created the flow naturally ends up with extra columns (at minimum, the ones used in the join clause). This requires an added clean step to remove/merge the duplicate. The problem is that once the clean step is added, you can't easily tell which column came from which side of the join. I think it would be much more intuitive if you could remove the columns within the Join node.
